Abstract

The purposes of this study were: (1) to clone the cDNA encoding pituitary thyroid-stimulating hormone beta subunit (TSH β) of the Japanese eel, *Anguilla japonica*, together with its genomic DNA sequence, for phylogenetic analysis, and to study the regulation of the TSH β gene expression in cultured pituitaries; and (2) to investigate the transcript levels of pituitary TSH β mRNA and the serum thyroxine profiles at different stages of ovarian development before and during silvering in the wild female eels. The maturity of female eels was divided into four stages, juvenile, sub-adult, pre-silver, and silver, based on skin color and oocyte diameter. The genomic DNA of the TSH β subunit contains two introns and three exons, and the TSH β protein possesses a putative signal peptide of 20 amino acids and a mature peptide of 127 amino acids. The amino acid sequence identities of TSH β mature peptide of Japanese eel compared with those of teleosts and other vertebrates are: European eel (98.4%), salmonids (60.6 – 61.3%), carps (52.0 – 56.7%), sturgeon (48.4%), and tetrapods (42.9 – 45.2%). In *in vitro* studies of the regulation of TSH β mRNA it was found that thyrotropin-releasing hormone increased while thyroxine decreased its expression. RT-PCR and real-time quantitative PCR analysis showed that the transcript levels of TSH β subunit increased during eel silvering. The serum thyroxine levels also increased in parallel with TSH β mRNA expression during silvering, supporting the hypothesis that the hypothalamus–pituitary–thyroid axis is correlated to silvering in the wild female Japanese eels.

Journal of Molecular Endocrinology (2004) **32**, 179–194

Introduction

The pituitary glycoprotein hormones in vertebrates include thyroid-stimulating hormone (thyrotropin, TSH), luteinizing hormone, and follicle-stimulating hormone, each consisting of two different subunits, α and β (Pierce & Parsons 1981). The α subunits are identical in a given species and are common to all pituitary glycoprotein hormones, while the β subunits are specific for each hormone and determine the hormonal activity and species specificity. The α and β subunits are initially formed as separate proteins by different genes, and

following glycosylation they are associated by non-covalent bonding to form biologically active hormonal molecules.

The synthesis and release of TSH is regulated by hypothalamic thyrotropin releasing hormone (TRH) and negative feedback is controlled by the thyroid hormones, triiodothyronine (T_3) and thyroxine (T_4); this comprises the hypothalamus–pituitary–thyroid (HPT) axis in vertebrates (McNabb 1992, Chatterjee *et al.* 2001). Thyroid hormones are essential for development, growth, metabolism, behavior, and reproduction in vertebrates (Gorbman *et al.* 1983). Thyroid hormones

Figure 1 Procedures of RT-PCR sequencing of TSH β subunit genomic DNA (upper) and cDNA (lower) from pituitary glands of the Japanese eel. Numbers of primers (P) indicate the corresponding oligonucleotides listed in Materials and methods.

have long been implicated in the migration of anadromous salmonids. They are required for the preparatory transformation of parr to a seawater-tolerant smolt, and are thought to stimulate migratory behavior (Boeuf 1994). In juvenile salmonids, there is an indication that thyroid hormones are involved in the body silvering process by depositing guanine in the skin (Ikuta *et al.* 1985, Ura *et al.* 1994). In conger eel, *Conger myriaster*, thyroid hormones are important in the regulation of metamorphosis from the leptocephalus to the elver (Yamano *et al.* 1991). The HPT axis is also closely correlated to reproduction. A significant temporal relationship exists for most species of teleosts between thyroid status and gonadal status over at least certain phases of the reproductive cycle (Cyr & Eales 1996). Based on the studies of several teleost species, it was thought that the thyroidal activity usually increases during early gonadal development, is maintained or enhanced during the period of reproduction, and commonly decreases during or after spawning (Cyr & Eales 1996).

The Japanese eel, *Anguilla japonica* Temminck and Schlegel, is a catadromous fish with a complex life cycle that includes both marine and freshwater habitats (Tesch 1977). After living in rivers for years, eels undergo pronounced morphological and physiological changes from yellow to silver eels (also known as 'silvering') (Tesch 1977, Lokman & Young 1998a,b). The modifications include skin color changing from white/yellow to silver on the belly and from green to black on the back, downstream migration behavior, and rapid

development of the gonad. Accordingly, the HPT axis may be involved in eel silvering. However, no information is yet available with respect to the corresponding changes in thyroid status during silvering of Japanese eels. We therefore investigated the changes in the pituitary–thyroid axis during silvering of wild Japanese eels. As a direct assay of eel TSH is unavailable as yet, the TSH β transcript levels were estimated to represent thyrotropin expression activity from the pituitary. The circulating thyroxine levels were estimated to reflect the thyroid status. Since the genome and peptide sequence of TSH β for Japanese eel are not known yet, we also cloned the TSH β gene for phylogenetic analysis. We report here the cloning of the genomic and cDNA sequences for Japanese eel TSH β and its deduced peptide sequence, the regulation of TSH β mRNA expression, and the changes in TSH β mRNA expression levels together with circulating thyroxine levels at various stages of ovarian development during silvering of wild female Japanese eels.

Materials and methods

cDNA cloning of the Japanese eel TSH β subunit

Design of oligonucleotide primers

Oligonucleotides, used as PCR primers for amplification of the TSH cDNA and genomic DNA of the Japanese eel, are listed below and shown in Fig. 1. The sense primer (SP: 5'→3') and antisense primer (ASP: 3'→5') were designed from

the conserved coding region of the TSH β cDNA of the European eel and other teleosts. The β actin sequence of the Japanese eel was cloned in our laboratory.

Primer 1, SP for TSH β subunit: 5'-ATGAGAG TGGTCCTGTTGGCC-3'; primer 2, ASP for TSH β subunit: 5'-GGATGTGGTTGCTCTGT CCCGG-3'. Primer 3, SP for 3'-rapid amplification of cDNA ends (RACE): 5'-GATCCGGCG CGGGACGAGTG-3'; primer 4, ASP for 5'-RACE: 5'-CCATGCAGATGGTGGTGTGA-3'. Primer 5, SP for TSH β subunit: 5'-GACA CTCGGAGAAAATTCTAC-3'; primer 6, SP for TSH β subunit: 5'-CTTCTGCGTGGCCAT CAACACCA-3'; primer 7, ASP for TSH β subunit: 5'-CACTCGTCCCGCGCCGGATC-3'. Adapter primer (AP) for 3'-RACE: 5'-GGCCACGCGTCGACTAGTACTTTTTTTTTT TTTTTTTT-3'. Abridged universal amplification primer (AUP) for 3'-RACE: 5'-GGCCACGC GTCGACTAGTAC-3'. Abridged anchor primer (AAP) for 5'-RACE: 5'-GGCCACGCGTCGACT AGTACGGG I IGGGI IGGG I IG-3', where I is the base inosine. Primer of SP for β -actin subunit: 5'-GCTGTCCCTGTATGCCTCTGG-3'; primer of ASP for β -actin subunit: 5'-GTCAGGATCTT CATGAGGTAGTC-3'.

RT-PCR for TSH β cDNA sequence and RACE

Fresh pituitary glands were collected from the cultured Japanese eels reared in the laboratory. Total RNA was then extracted using the total RNA miniprep system kit (Viogene, Sunnyval, CA, USA). The concentration and quality of the extracted RNA were measured at A260 nm/A280 nm (Kontron Spectrophotometer, UVIKON 810). Complementary DNA was synthesized using oligo-d(T)₁₈ primer (100 ng) and moloney murine leukemia virus-reverse transcriptase (MMLV-RT) (Stratagene, La Jolla, CA, USA) following instructions recommended by the manufacturer. Reverse transcription was performed for 35 min at 42 °C and later at 70 °C for 10 min to heat-inactivate the MMLV-RT.

The PCR was performed in 50 μ l final volume with 2.5 U Taq DNA polymerase (Gibco BRL, Gaithersburg, MD, USA) using primers 1 and 2 (100 ng for each). After an initial 3 min denaturing step at 94 °C, 35 cycles of amplification were performed using a cycle profile of 94 °C for 1 min,

62 °C for 40 s, and 72 °C for 1 min. Elongation was extended to 10 min at 72 °C after the last cycle. The PCR products were sequenced commercially with an ABI 377 automated sequencer (Perkin-Elmer Applied Biosystems).

The remaining 5' and 3' untranslated region (UTR) sequences were obtained by RACE using the RACE kit (Gibco BRL). Briefly, 1 μ g of the pituitary total RNA was reverse-transcribed using primer AP by 200 U Superscript II reverse transcriptase, followed by PCR between primer 3 and the AUP. For 5'-RACE, 1 μ g of the pituitary total RNA was first reverse-transcribed by 200 U Superscript II reverse transcriptase with primer 2. The acquired single strand cDNA was column purified and then oligo-dC tailed using terminal deoxynucleotidyl transferase. PCR was then performed using primer 4 and the AAP.

Total DNA extraction and PCR for TSH β genomic DNA

The total genomic DNA of the Japanese eel was extracted from the liver using the total DNA miniprep system kit (Viogene). The TSH β genomic DNA sequence was obtained by PCR with primers 5 and 7, located in the head of the 5'-UTR and the end position of the coding region of TSH β cDNA respectively. Intron sequences were obtained by re-amplifying the PCR product with primers 4 and 5 for intron I and primers 6 and 7 for intron II.

Regulation of TSH β mRNA expression

Cultured Japanese eels ($n=27$) at the yellow stage, reared in the laboratory for 2 years, were used for studying the regulation of TSH β mRNA. Pituitary tissue culture was carried out based on the procedures described by Gregory and Porter (1997) with some modifications. Pituitaries were collected from the Japanese eels, immediately washed twice in 1 $\times$ Hanks buffer and placed in 35 mm culture dishes. Each pituitary was sliced into 4 pieces, incubated in 1.5 ml M-199 (Sigma) containing 25 mM HEPES, 4 mM NaHCO₃, 0.1% BSA and antibiotics (penicillin and streptomycin), and treated with saline (control group), TRH (pGlu-His-Pro-NH₂, 10⁻⁸M), or T₄ (10⁻⁸M). All the dishes were kept in a CO₂ incubator maintained under 3.5% CO₂ concentration at 30 °C for 6 h. After centrifugation, the total RNAs were isolated

from the tissues. The RNA was reverse transcribed as described and the cDNA was PCR amplified using TSH β primers 1 and 7. As an internal control in the RT-PCR reactions, β actin was also amplified simultaneously for normalization. An optimal PCR amplification cycle (25 cycles) was chosen to observe the different cDNA levels based on parallelism of different PCR cycles (15, 20, 25, and 30 cycles). PCR products were analyzed by 2.5% agarose gel electrophoresis. To validate the mRNA levels estimated by RT-PCR analysis, two samples of each treatment were tested for real-time quantitative PCR using the fluorescence dye SYBR Green 1 (Morrison *et al.* 1998).

Transcript levels of TSH β mRNA at different stages of ovarian development of wild female Japanese eels

Collection of wild eels and classification of maturing status

Wild female Japanese eels (*n*=46) were collected by eel traps in the estuary of the Kaoping River in southwest Taiwan (120° 50' E and 22° 40' N) (Table 1). Males were difficult to collect because the sex ratio was skewed to females (Tzeng *et al.* 2002); thus, only females were considered in this study. These eel samples have previously been used for investigation of gonadotropin mRNA transcript levels (Han *et al.* 2003a). The eels were stunned by ice before morphometric measurement. Total length (TL, ±0.1 cm) and body weight (BW, ±0.1 g) of the eels were measured before

decapitation for blood collection. The sex of each eel was determined by histology of the gonad. The gonad weight (GW, ±0.01 g) and digestive tract weight (DW, ±0.01 g) were measured and the gonadosomatic index (GSI) and digestosomatic index (DSI) were estimated according to the formulae, $GSI=100 \times [GW \text{ (g)}/BW \text{ (g)}]$ and $DSI=100 \times [DW \text{ (g)}/BW \text{ (g)}]$ respectively. Oocyte diameters (OD, ±1 μm) were calculated according to Yamamoto *et al.* (1974).

In our previous investigation, the maturity of the wild female Japanese eels before and during silvering were divided into three stages (yellow, pre-silver and silver) based on skin color and histological observations of ovarian development (Han *et al.* 2003b). In the present study, the yellow eels were further divided into juvenile and sub-adult stages based on OD for better comparison (Table 1). The GSI and OD of the female Japanese eel were significantly different among different ovarian developmental stages (*P*<0.05, Table 1). Ovaries of juvenile eels contained mainly stage II (chromatin nucleolus stage) oocytes (<50 μm). The ovaries of sub-adult eels also contained stage II (chromatin nucleolus stage) oocytes predominantly, but with larger OD (50–90 μm) (Table 1). In the pre-silver eels, the oocytes (90–130 μm) grew rapidly and were mainly in stage III (peri-nucleolus stage). The initial oil drops became apparent at the periphery of the oocytes. In the silver eels, the oocytes (>130 μm) continued to grow, and the oil drops accumulated and filled the whole cytoplasm. They were mainly in stage IV (oil-drop stage) (Han *et al.* 2003b).

Figure 2 cDNA nucleotide and deduced amino acid sequences of the Japanese eel TSH β subunit. In the right-hand column, upper numbers refer to the nucleotide sequence and lower numbers refer to the amino acid sequence. The start (ATG) and stop (TAG, indicated by an asterisk) codons are shown by boxes. The two arrows show, respectively, the introns 1 and 2 insertion sites.

Measurement of pituitary TSH β mRNA levels

Total RNA (1 μ g) from individual pituitaries of wild female Japanese eels of juvenile ($n=11$), sub-adult ($n=17$), pre-silver ($n=9$), and silver ($n=9$) stages was reverse-transcribed using oligo-d(T)₁₈ primer (100 ng) and MMLV-RT (Stratagene) following instructions recommended by the manufacturer. PCR reactions for TSH β were performed using primers 1 and 7 with 25 cycles. As an internal control in the RT-PCR reactions, β actin was also amplified simultaneously for normalization. To validate the reliability of RT-PCR analysis, two pituitaries of eels selected from each ovarian stage were analyzed by real-time quantitative PCR as described.

Radioimmunoassay (RIA) of serum thyroxine levels of wild female Japanese eels at different stages of ovarian development

Measurement of serum thyroxine (T_4) was performed by commercial kits (Diagnostic System Laboratories, Texas, USA). The cross-reactivity of the T_4 antibody was measured for thyroxine (100%), triiodothyroacetic acid (1.13%), triiodothyronine (0.91%), diiodothyronine (0.03%), and other related hormones which were not detectable. The

minimum detection limit was 4 ng/ml serum. Since the collected blood of juvenile eels was insufficient for RIA analysis, only the other three stages of female Japanese eels were used for serum T_4 measurement in the present study.

Statistical analysis

Differences among the eel stages of the morphometric indexes or the transcript levels of TSH β mRNA were analyzed by one-way analysis of variance (ANOVA) followed by Tukey's HSD (Honestly Significantly Different) test. Significance level was considered to be at $P<0.05$.

Results

Sequence analysis of the Japanese eel TSH β cDNA and genomic DNA

The acquired TSH β cDNA of Japanese eel was 703 bp in total length, including 81 bp of the 5'-UTR, 444 bp of the coding region, and 178 bp of partial 3'-UTR (Fig. 2). The agarose gel analysis of the PCR products of TSH β 3'-RACE showed multiple bands, thus the full 3'-UTR sequence was difficult to obtain. The coding region encodes a putative protein of 147 amino acids, which contains

a signal peptide of 20 amino acids and a mature peptide of 127 amino acids (Fig. 2).

The genomic DNA sequence of the TSH β subunit was PCR amplified by primers 4, 5, 6 and 7. The acquired sequences were compared with that of the TSH β subunit cDNA for identification of the introns (Fig. 3). Two introns were observed; intron 1 was located in the 5'-UTR (Fig. 2), which included 484 bp (Fig. 3) while intron 2 (including 860 bp, Fig. 3) was within the coding region (Fig. 2). Both introns started with a gt base pair and ended with an ag base pair. We only found one form of intron I and II in the TSH β genomic DNA as indicated by only one band of PCR product of TSH β genomic DNA amplified from primers 5 and 7.

Regulation of the TSH- β gene expression

The experiment on the regulation of mRNA of the TSH β showed that TRH at 10^{-8} M significantly increased its expression ($P < 0.001$), while T_4 at

10^{-8} M significantly decreased its expression ($P < 0.001$) (Fig. 4). Representative real-time quantitative PCR for TSH β mRNA expressions at different treatments is shown in Fig. 5(A). The calculated expression levels of TSH β mRNA estimated by real-time quantitative PCR were comparable to the corresponding mRNA levels estimated by the RT-PCR analysis.

Changes in TSH β mRNA expression levels at different ovarian stages of wild Japanese eel

The expression of TSH β mRNA levels at different stages of ovarian development is shown in Fig. 6. The results were normalized with data from densitometric scanning of a constitutively expressed protein β actin. As indicated, TSH β mRNA levels gradually increased with ovarian development ($F = 3.12 > F_{(0.05, 26)} = 3.03$, $P = 0.048$), and the differences were significant between silver and juvenile/sub-adult stages ($P < 0.05$). Representative

(A) Total RNA preparation and agarose gel analysis were the same as in Fig. 4. β actin was used as a control in each column. (B) The band intensities of β subunits from juvenile, sub-adult, pre-silver, and silver stages. The value of the juvenile group was considered as 1 and values of other stages were calculated with respect to the juvenile group. Different letters above the bars indicate that the differences are statistically significant ($P < 0.05$). Numbers inside the bars represent sample size.

Serum thyroxine levels at different ovarian stages of wild Japanese eel

Mean serum T_4 levels gradually increased during eel silvering, with 9.17 ± 0.92 ng/ml in sub-adult,

12.01 ± 1.53 ng/ml in pre-silver, and 14.96 ± 1.57 ng/ml in silver females respectively. Significant differences were found among eel stages ($F = 5.61 > F_{(0.05, 34)} = 3.29$, $P < 0.01$), and the

Figure 7 Serum thyroxine levels at different ovarian stages of the wild female Japanese eels. Different letters above the bars indicate that the differences are statistically significant ($P < 0.05$). Numbers inside the bars represent sample size.

differences were significant between silver females and sub-adult female eels ($P < 0.05$) (Fig. 7).

Discussion

Comparisons of protein sequences of Japanese eel TSH β with teleosts and other vertebrates are shown in Fig. 8. As indicated, positions of all 12 cysteine residues, forming six-disulfide bonds within the β subunits, and one asparagine-linked glycosylation site between cysteine 3 and 4, are conserved in all vertebrates. Differences of two amino acids in the mature peptide of TSH β are observed between Japanese eel and European eel (98.4% of identity) while a one amino acid difference exists in the signal peptide between the two eels (95% of identity) (Table 2 and Fig. 8). The amino acid identities of TSH β mature peptide of Japanese eel compared with teleostean species from other orders range from 48.4% to 61.3%, and compared with tetrapods they range from 42.9 to 45.2% (Table 2). Such findings demonstrate that a high degree of diversity exists in the TSH β peptide sequence among different teleostean orders, and between teleosts and tetrapods, indicating the low degree of conservation of the TSH β amino acid sequence in vertebrates during evolution. The

results also indicate that the intra-order homology of TSH β (ex. Japanese eel vs European eel) is greater than the homology of inter-order (ex. anguillids vs salmonids), which in turn is greater than the homology of inter-animal class (ex. teleosts vs mammals). The phylogenetic tree of amino acid sequences of TSH β mature peptides of the vertebrates, constructed by the Neighbor-Joining method, indicates that TSH β subunits from different species of the same animal class are grouped together in accordance with the known phylogenetic orders (Fig. 9). As indicated, the Chondrosteian sturgeon is closer to the tetrapods than the teleosts; such findings are similar to the results reported by Qurat *et al.* (2000).

The sequence identity of TSH β signal peptide for Japanese eel is high in comparison with European eel (95%), but below 40% when compared with other species (Table 2). It is interesting to note that the percentage identities of TSH β signal peptide between Japanese eel and other vertebrates are always lower than the corresponding identities of TSH β mature peptide (Table 2), indicating that the signal peptide is less conserved than the mature peptide of TSH β during evolution. On the other hand, the genetic structure of TSH β of the Japanese eel contains

Figure 8 A comparison of the amino acid sequence of TSH β of the Japanese eel with other species. The species and their accession numbers of the GenBank or published papers are: Japanese eel (*Anguilla japonica*, AY158008), European eel (*Anguilla anguilla*, Paradet-Balade *et al.* 1998), Atlantic salmon (*Salmo salar*, 073824), rainbow trout (*Oncorhynchus mykiss*, Ito *et al.* 1993), common carp (*Cyprinus carpio*, BAA20082), bighead carp (*Aristichthys nobilis*, Chatterjee *et al.* 2001), goldfish (*Carassius auratus*, Sohn *et al.* 1999), Siberian sturgeon (*Acipenser baerii*, Quérat *et al.* 2000), rat (*Rattus norvegicus*, Carr *et al.* 1987), human (*Homo sapiens*, Hayashizaki *et al.* 1985), chicken (*Gallus gallus*, Gregory & Porter 1997), duck (*Cairina moschata*, Hsieh *et al.* 2000), toad (*Xenopus laevis*, Buckbinder & Brown 1993). The signal peptide sequence is underlined. The dots represent amino acids that are identical to Japanese eel, and the dashes are included to improve the alignment. The twelve conserved cysteine residues are denoted by asterisks, and the one asparagine-linked glycosylation site is denoted by a cross.

Table 2 Comparison of percentage identity of signal and mature TSH β peptides between Japanese eel and other vertebrates

Species*	Signal peptide (%)	Mature peptide (%)
Japanese eel	100.0	100.0
European eel	95.0	98.4
Atlantic salmon	35.0	61.3
Rainbow trout	35.0	60.6
Common carp	21.1	56.7
Bighead carp	31.6	52.8
Goldfish	21.1	52.0
Siberian sturgeon	35.0	48.4
Toad	33.3	45.2
Chicken	30.0	44.3
Duck	30.0	44.3
Rat	40.0	43.7
Human	35.0	42.9

*The accession numbers of the GenBank and references are indicated in the legend of Fig. 8.

three exons and two introns, the same as the rat (Carr *et al.* 1987), goldfish (Sohn *et al.* 1999), and European eel (Paradet-Balade *et al.* 1998). The positions of intron I are all located in the 5'-UTR, and the insertion sites of intron II are all located within the coding region of the comparable positions. The length and nucleotide sequence of the corresponding introns are highly variable among vertebrates. For example, the lengths of intron II in the Japanese eel, European eel, goldfish and rat are 860, 533/681, 299 and 377 bp respectively, indicating their low conservation among vertebrates.

Previous study in European eel shows that there is only one copy of the TSH β gene in each individual but with multiple forms of alleles, and the polymorphism of TSH β occurring in the regions of intron II and 3'-UTR is due to the different numbers of minisatellites (Paradet-Balade *et al.* 1998). Therefore, heterogeneities of TSH β mRNA in length among individual eels were detected by Northern blot analysis (Paradet-Balade *et al.* 1997, 1998). In the present study, the multiple bands of the 3'-RACE PCR product of TSH β cDNA in the Japanese eels may be due to the heterogeneity of 3'-UTR, as in the case of the European eel. We also observed that the single cDNA band amplified from the coding region of TSH β , obtained by RT-PCR analysis from the present study, should facilitate the quantification of

TSH β mRNA as compared with the single or double bands of TSH β mRNA with various lengths obtained by Northern blot analysis.

TRH is a major hypothalamic simulating hormone for the secretion of pituitary TSH in mammals (Prasad 1985). In the teleosts, the presence of immunoreactive TRH has been found in common carp (Hamano *et al.* 1990), sea bass (Batten *et al.* 1990), and chinook salmon (Matz & Takahashi 1994). Recently, the stimulatory effect of TRH on the TSH β mRNA expression has been reported in bighead carp (Chatterjee *et al.* 2001). In the present study, TRH was also found to increase the level of TSH β mRNA (Fig. 4). In contrast, thyroid hormones have been shown to directly depress TSH β mRNA levels from pituitaries under *in vitro* cultured conditions of various tetrapods (Croyl & Maurer 1984, McNabb 1992, Hsieh *et al.* 2000) and teleosts (Pradet-Balade *et al.* 1997, Chatterjee *et al.* 2001). In the present study, we also demonstrated that T_4 depressed TSH β mRNA expression in the pituitary culture of Japanese eel (Fig. 4). As indicated, a rather modest response of the TSH β mRNA expression was obtained in the present study; incubation of the Japanese eel pituitary fragments with TRH and T_4 at 10^{-8} M for 6 h at 30 °C resulted in a 52% increase and a 25% decrease in TSH β mRNA expression respectively, compared with the control (Fig. 4). In the pituitary cell culture of the European eel, it was demonstrated that treatment with T_3 or T_4 at 10^{-8} M for 14 days at 18 °C resulted in a 70% decrease in TSH β mRNA expression compared with the control (Pradet-Balade *et al.* 1997). We have also shown that after treatment of the bighead carp pituitary fragments with TRH and T_4 at 10^{-8} M for 36 h at 20 °C, the TSH β mRNA expressions were 75% higher and 40% lower, respectively, than the control (Chatterjee *et al.* 2001). The findings of these studies demonstrated that the *in vitro* response of TSH β mRNA expression to TRH or thyroid hormones varied with different incubation conditions of the pituitary, such as tissue or cell culture, incubation temperature and time length, and other factors. In mammalian studies, it has been demonstrated that TRH stimulates TRH production by effects at the transcriptional and secretory levels. The TRH-response regions have been identified in the TSH β subunit gene promoter (Sarapura *et al.* 1995). It has also been established in mammals that TSH α and

Figure 9 A phylogenetic tree of the putative mature peptide sequences of the TSH β subunits from teleosts and selected species of tetrapods. The tree was constructed with the Neighbor-Joining method by the MEGA 2 program. The numbers indicate the bootstrap robustness from 1000 replicates. The top sequence of the *A. japonica* was from this study, and those of other sequences were from published papers and the accession numbers of the GenBank as indicated in the legend to Fig. 8.

TSH β subunit genes contain thyroid response elements that mediate their transcriptions by the thyroid hormone–receptor complex (Chin *et al.* 1993). A thyroid-response element was also identified in the α subunit gene of Chinook salmon (Suzuki *et al.* 1995). Thus, the specific mechanism whereby TRH and thyroid hormones regulate TSH mRNA expression in teleosts is likely to resemble that found in mammals.

As indicated in the present study, the steady-state TSH β mRNA levels in the pituitaries were increased with advancement of the silvering process. Such patterns were in parallel with the increasing levels of serum thyroxine. Since the quantification of TSH in teleosts is not available yet, the TSH levels in the pituitary and in the

circulation remain unknown. The steady-state TSH β mRNA levels estimated in the pituitaries may reflect TSH formation activity. Thus, the increased TSH formation in the pituitary during the eel silvering process leads to increased formation and release of thyroxine from thyroid tissues. In mammals, regulation of TSH gene expression, formation and secretion is well established (Sarapura *et al.* 1995). The formation and secretion of pituitary TSH is up-regulated by hypothalamic TRH and down-regulated by thyroid hormones via feedback mechanisms (Sarapura *et al.* 1995). However, TSH is also regulated by other hormones secreted from the hypothalamus and other tissues, e.g. somatostatin, dopamine, glucocorticoids (Sarapura *et al.* 1995, Schwartz 2000). Thus

the regulation of TSH appears to be highly complex.

In *Anguilla australis*, injection of androgen (11-ketotestosterone) into females is found to induce some silvering-related morphological changes (Rohr *et al.* 2001). In the Japanese eel, the morphological changes, such as silver skin and dark pectoral fins, enlarged eyes, and degenerative digestive tract, are found to be synchronous with gonadal development during the silvering process (Han *et al.* 2003b), and the mRNA expression of both gonadotropin I β and gonadotropin II β is significantly higher in the silver stage compared with the yellow stage (Han *et al.* 2003a). When the freshwater-reared yellow Japanese eels were induced to become silver eels by repeated injection of human chorionic gonadotropin (hCG), similar morphological and physiological changes were observed (YS Han, WN Tzeng and IC Lia, unpublished data). All this evidence indicated that the gonadotropin and sex steroids play an important role during eel silvering. In female rainbow trout, the increase in the gonadosomatic index was greater when the fish were treated with T₃ and gonadotropin in combination than when treated with gonadotropin alone (Cyr & Eales 1988). In the thecal cell culture of brook trout ovary, treatment with gonadotropin plus T₃ caused a more significant increase in testosterone than treatment with gonadotropin alone (Cyr & Eales 1996). Thus, thyroid hormones are undoubtedly involved in synergizing with gonadotropin during oocyte maturation. The existence of a thyroid hormone receptor in the gonad has also been proved in several teleosts such as perch (Chakraborti *et al.* 1986) and medaka (Soyano *et al.* 1993). This permits the enhancement of thyroid hormone on gonadotropin action. In the present study, the silvering eels were in the early gonadal development stage (Table 1). The higher activity of the pituitary–thyroid axis may synergize with the pituitary–gonad axis, as in other teleosts, to promote ovarian development during eel silvering.

In the wild arctic char, the blood thyroxine concentration is twice as high in upstream and downstream migrants as in non-migrants (Høgåsen & Prunet 1997), and the underyearling sockeye salmon shows a natural surge in T₄ before downstream migration occurs (Boeuf 1994). Thyroid hormone treatment could change the swimming direction of chum salmon fry to

downstream (Boeuf 1994, Iwata 1995). Our previous study also found that, during silvering, the Japanese eel migrated from freshwater to seawater (Han *et al.* 2003c). As indicated in the present study, the expression of TSH β mRNA was increased significantly (Fig. 6), in parallel to that of serum T₄ levels during silvering of female eels (Fig. 7). Accordingly, the more active HPT axis in silver female eels might also be related to the downstream migration behavior of the silver eels.

When the freshwater-reared yellow Japanese eels were induced to become silver eels by injection of hCG, the appearance of the silver color seems to be later in hCG-induced eels than in the wild eels (YS Han, WN Tzeng and IC Lia, unpublished data). This implies that some other factors may also be involved in the body silvering of the eels in addition to hormones of the hypothalamus–pituitary–gonad (HPG) axis. In the masu salmon, thyroid hormone treatment could promote guanine deposition in the skin during bodily silvering in smoltification (Ikuta *et al.* 1985, Ura *et al.* 1994). In the European eel, the dispersal of purines in the skin was thought to cause a silver color on the belly of silver stage eels (Pankhurst & Lythgoe 1982). These findings suggest that thyroid hormones may synergize with the HPG axis in causing silver skin coloration during the silvering process of the Japanese eel.

In conclusion, we have cloned both cDNA and genomic DNA of the TSH β subunit of Japanese eel. The transcript levels of TSH β mRNA were increased during eel silvering, and were parallel with the increased serum thyroxine levels. These results suggest that the HPT axis may play a role in the silvering process of the Japanese eel.
