Abstract

11β-hydroxysteroid dehydrogenase type 1 (11β-HSD1) controls the production of active glucocorticoid (GC) and has been proposed as a new target for the treatment of type 2 diabetes. We have previously reported that a natural product, curcumin, exhibited moderate inhibition and selectivity on 11β-HSD1. By analyzing the models of protein, microsome, cells and GCs-induced mice in vitro and in vivo, this study presented a novel curcumin analog, LG13, as a potent selective 11β-HSD1 inhibitor. In vivo, Type 2 diabetic mice were treated with LG13 for 42 days to assess the pharmacological benefits of 11β-HSD1 inhibitor on hepatic glucose metabolism. In vitro studies revealed that LG13 selectively inhibited 11β-HSD1 with IC50 values at nanomolar level and high selectivity over 11β-HSD2. Targeting 11β-HSD1, LG13 could inhibit prednisone-induced adverse changes in mice, but had no effects on dexamethasone-induced ones. Further, the 11β-HSD1 inhibitors also suppressed 11β-HSD1 and GR expression, indicating a possible positive feedback system in the 11β-HSD1/GR cycle. In type 2 diabetic mice induced by high fat diet plus low-dosage STZ injection, oral administration with LG13 for 6 weeks significantly decreased fasting blood glucose, hepatic glucose metabolism, structural disorders, and lipid deposits. LG13 exhibited better pharmacological effects in vivo than insulin sensitizer pioglitazone and potential 11β-HSD1 inhibitor PF-915275. These pharmacological and mechanistic insights on LG13 also provide us novel agents, leading structures, and strategy for the development of 11β-HSD1 inhibitors treating metabolic syndromes.

Introduction

Glucocorticoid (GC) hormones are important metabolic regulators. Recent investigations have indicated that GC excess in tissues such as liver and adipose tissue contributes to the development of metabolic syndrome, whose characteristics include central obesity, insulin resistance, atherogenic dyslipidemia, and hypertension (Masuzaki et al. 2001, Morton et al. 2005, Walker 2006, Macfarlane et al. 2008). 11β-hydroxysteroid
dehydrogenase (11β-HSD) type 1, which catalyses the conversion of active GCs (cortisol in humans and corticosterone in rodents) from their inactive 11-keto metabolites (cortisone in humans and 11-dehydrocorticosterone in rodents), can amplify the local level and activity of GCs (Masuzaki et al. 2001, Nixon et al. 2012, Chapman et al. 2013). On the other hand, 11β-HSD2, as another isoform of 11β-HSDs, catalyzes the opposite reaction, converting corticosterone to 11-dehydrocorticosterone in rodents (Chapman et al. 2013). Given that 11β-HSD1 is abundantly expressed in metabolically important tissues which become resistant to insulin action in type 2 diabetes, such as adipose, muscle, and liver tissue (Chapman et al. 2013), inhibition of 11β-HSD1 offers the ability to restore the metabolic action of insulin in these tissues. Furthermore, the lowering of intracellular GC concentration through a variety of means, including the administration of small molecular 11β-HSD1 inhibitors, significantly attenuates the signs and symptoms of disease in animal models and in patients with diabetes/metabolic syndrome (Tahrani et al. 2011, Nixon et al. 2012, Harno et al. 2013a). In recent decades, a number of small molecule inhibitors of 11β-HSD1 have been discovered, and several molecules have been evaluated in clinical trials. Several small molecule inhibitors of 11β-HSD1 were discovered in natural products, including glycyrrhetinic acid, carbenoxolone, gossypol and estradiol (Cohen 2005, Zhang et al. 2009, Prasad Sakamuri et al. 2012). However, these natural products often showed low selectivity in the inhibition of 11β-HSD1 over 11β-HSD2. Thus, the development of synthetic structural analogs of natural products via rational drug design may be one approach for overcoming this low selectivity by finding new 11β-HSD1-targeting candidates. Recently, RS Ge’s group reported that curcumin, the main active component of turmeric isolated from the plant Curcuma Longa, exhibited potent inhibition of human and rat 11β-HSD1 in intact cells, with a two- to fivefold selectivity compared to 11β-HSD2 (Hu et al. 2013). Our lab has long been engaged in curcumin-based drug design and discovery. We have designed and synthesized a series of mono-carbonyl curcumin analogues, which exhibited promising pharmacokinetic profiles (Liang et al. 2009a). As a part of a research collaboration, RS Ge’s group also screened a series of curcumin analogs provided by our lab and found that some compounds specifically inhibited 11β-HSD1 activity with much greater potency (with the IC50 in nanomolar range) and much higher selectivity (with >100-fold more than 11β-HSD2) than curcumin (Lin et al. 2013). Our previous studies reported the 11β-HSD1-inhibitory activity of 40 curcumin analogs, indicating that curcumin analogs may become novel therapeutic agents targeting 11β-HSD1 for the treatment of metabolic syndrome.

Among our curcumin analogs which have been tested for 11β-HSD1 inhibition, (2E,6E)-2,6-bis(2-(trifluoromethyl)benzylidene)cyclohexanone (LG13, Fig. 1A), shows the strongest activity in vitro and it also has a high selectivity compared to 11β-HSD2. The aim of the present study was to examine the cellular target of LG13 and its pharmacological effects in type 2 diabetic mice. We also investigated that specific inhibition of 11β-HSD1 is a promising therapeutic strategy for type 2 diabetes and metabolic syndrome.

Materials and methods

Reagents

Glucose, dexamethasone, prednisone, and the GC receptor (GR) selective inhibitor, mifepristone were purchased from Sigma. Corticosterone, 11-dehydrocorticosterone, NADP+, and NADPH were bought from Aladdin (Shanghai, China). Compound LG13 was synthesized in our lab using the method described in a previous publication (Liang et al. 2009b). Before being used for biological experiments, LG13 was recrystallized from CHCl3/EtOH, and then HPLC was used to determine its purity (99.31%). The structures of curcumin and LG13 are shown in Fig. 1A. LG13 was dissolved in DMSO for in vitro experiments and was in 1% CMC-Na for in vivo experiments. Antibodies anti-11β-HSD1 (sc-20175, dilution 1:400), anti-GR (sc-376426, dilution 1:500), and anti-AKT (sc-377457, dilution 1:300) were purchased from Santa Cruz Biotechnology; antibodies anti-pAKT (4060S, dilution 1:200) and anti-GAPDH (5174S, dilution 1:1000) were from Cell Signaling Technology (Danvers, MA, USA). The 11β-HSD1 selective inhibitor PF-915275 was purchased from Tocris Bioscience (Abingdon, UK). Recombined human 11β-HSD1 protein was produced by our lab and characterized by western blot and enzyme activity assay. Biochemical index analysis kits for total cholesterol (Tch), triglyceride (TG), LDL-c, alanine transaminase (ALT), and aspartate amino-transferase (AST) were purchased from Jiancheng Biotechnology Company (Nanjing, China).

Cell culture

Human hepatic cell line HL-7702 was obtained from the Institute of Biochemistry and Cell Biology, CAS (Shanghai, China). Cells were maintained in RPMI 1640
supplemented with 10% heat-inactivated FBS in humidified 37°C and 5% CO2 condition. Chinese hamary ovary cell line with overexpression of HSD11B1 gene (CHO-hs-HSD11B1 cells) was a gift from Prof. Renshan Ge (Population Council, New York, NY, USA) and cultured in DMEM medium supplemented with 10% heat-inactivated FBS in humidified 37°C and 5% CO2 condition.

**11β-HSD1/2 activity assay in cells and microsomes**

Isolation of rat leydig cells, preparation of rat testis microsomes and rat kidney microsomes, and the determination of 11β-HSD1/2 enzymatic activities was performed using the methods described previously (Hu et al. 2013).

**Molecular modeling**

Tripos molecular modeling package Sybyl-x.v1.1.083 (Tripos, St Louis, MO, USA) was employed for the docking study. The crystal structure of 11β-HSD1 was cited from the Protein Data Bank (PDB No. 2IRW), and residues around the ligand in this structure at a radius of 5 Å were isolated for construction of the docking grids. During the docking calculations, the ligand-binding groove on the proteins was kept rigid, whereas all torsible bonds of LG13 were allowed to rotate. The inhibitor binding affinities were estimated using the calculated binding free energy.

**Figure 1**

LG13 exhibited selective inhibition on 11β-HSD1 enzyme activity.

(A) Chemical structure of LG13.  (B) 11β-HSD1 inhibition of LG13 in vitro. Potency of LG13 against 11β-HSD1 and 11β-HSD2 enzymatic activities was determined as described in ‘Materials and methods’ section, and the IC50 was determined from more than ten determinations for each enzyme. (C) The inhibition of LG13 on recombinant 11β-HSD1 reductase was analyzed via HPLC method (D, E, and F). The predicted binding mode of LG13 to 11β-HSD1 was analyzed by computer-assisted molecular docking.
ligands were set free to allow flexible docking to produce more than 200 structures. The ligand–receptor binding energy was set to be approximately the sum of the van der Waals and electrostatic interaction energies. After an initial evaluation of the orientation and scoring, a grid-based minimization was carried out for the ligand to locate the nearest local energy minimum within the receptor binding site. Final docked conformations were clustered within the tolerance of 1 Å root-mean-square deviation.

Animals
Male C57BL/6j mice weighing 18–22 g were obtained from the Animal Centre of Wenzhou Medical University (Wenzhou, China). Animals were housed at 25 °C with a 12 h light:12 h darkness cycle and fed with a standard rodent diet and water. The animals were acclimatized to the laboratory for at least 10 days before use. Protocols involving the use of animals were approved by the Wenzhou Medical University Animal Policy and Welfare Committee (Approval Document NO. wydw2014-0018).

Effect of LG13 on prednisone- or dexamethasone-treated mice
Male C57BL/6j mice (8 weeks old) were randomly assigned to five groups based on body weight (n=8 in each group). The experimental groups and respective treatments were as follows: i) control (vehicle: 1% CMC-Na, orally); ii) prednisone acetate (3 mg/kg per day, i.p.); iii) prednisone acetate (3 mg/kg per day, oral); iv) dexamethasone (2.5 mg/kg per day, i.p.); and v) dexamethasone (2.5 mg/kg per day, oral). Prednisone or dexamethasone was administered i.p. once daily for 15 days to induce metabolic disorders. LG13 was administered by oral gavage treatment once per day with vehicle (1% CMC-Na), PF-915275 (5 mg/kg), pioglitazone (5 mg/kg), or LG13 (1 or 5 mg/kg), for 42 days. These mice continued to be fed their respective diets until the end of the study. The blood glucose levels of the mice were measured via blood drops obtained by clipping the tail of the mice using a ONE TOUCH BASIC plus Glucose Monitor (Lifescan, Milpitas, CA, USA). The blood glucose levels of these animals were recorded every week. An oral glucose tolerance test (OGTT) was carried out in mice deprived of food for 12 h (2 g/kg glucose administered by gavage) at day 41 of the treatment (Levy et al. 2014, Moreno et al. 2014). After the OGTT determination, the mice were killed under ether anesthesia at day 42 after drug treatment. Blood samples were collected via the retro–orbital sinus for the determination of a series of biochemical indexes. The livers were dissected, weighed, immediately frozen in liquid nitrogen and/or embedded in 4% paraformaldehyde for subsequent analysis. TG, TCh, LDL, ALT, and AST in serum or livers were analyzed using the respective kits with a colorimetric method (Hitachi 7020 Automatic Analyzer, Japan).

Liver histopathology
Liver tissues were fixed in 4% paraformaldehyde and embedded in paraffin. The paraffin sections (5 μm) were stained with hematoxylin and eosin (H&E). To estimate the extent of damage, the slides were observed under a light microscope (200×, Olympus).

Quantitative real-time PCR
Cells or liver tissues (50–100 mg) were homogenized in TRIZOL (Invitrogen) for the extraction of RNA according to the manufacturer’s protocol. Both reverse transcription and quantitative PCR were carried out using a two-step M-MLV Platinum SYBR Green qPCR SuperMix-UDG kit (Invitrogen). The Eppendorf realplex4 detection system (Eppendorf, Hamburg, Germany) was used for control group (Ctrl) and high fat diet (HFD) plus streptozotocin injection group. In detail, the control group was fed standard chow, and the others were given HFD with 40% fat content (Slac Laboratory Animal, Shanghai, China). Following 2 months of dietary intervention, the HFD group was injected intraperitoneally with a low dose of streptozotocin (50 mg/kg). After 1 week, mice with a fasting blood glucose level >14 mmol/l were considered to be diabetic. Diabetic mice (n=40) were assigned to five groups (n=8 in each group) and subjected to gavage treatment once per day with vehicle (1% CMC-Na), PF-915275 (5 mg/kg), pioglitazone (5 mg/kg), or LG13 (1 or 5 mg/kg), for 42 days. These mice continued to be fed their respective diets until the end of the study. The blood glucose levels of the mice were measured via blood drops obtained by clipping the tail of the mice using a ONE TOUCH BASIC plus Glucose Monitor (Lifescan, Milpitas, CA, USA). The blood glucose levels of these animals were recorded every week. An oral glucose tolerance test (OGTT) was carried out in mice deprived of food for 12 h (2 g/kg glucose administered by gavage) at day 41 of the treatment (Levy et al. 2014, Moreno et al. 2014). After the OGTT determination, the mice were killed under ether anesthesia at day 42 after drug treatment. Blood samples were collected via the retro–orbital sinus for the determination of a series of biochemical indexes. The livers were dissected, weighed, immediately frozen in liquid nitrogen and/or embedded in 4% paraformaldehyde for subsequent analysis. TG, TCh, LDL, ALT, and AST in serum or livers were analyzed using the respective kits with a colorimetric method (Hitachi 7020 Automatic Analyzer, Japan).

Liver histopathology
Liver tissues were fixed in 4% paraformaldehyde and embedded in paraffin. The paraffin sections (5 μm) were stained with hematoxylin and eosin (H&E). To estimate the extent of damage, the slides were observed under a light microscope (200×, Olympus).

Quantitative real-time PCR
Cells or liver tissues (50–100 mg) were homogenized in TRIZOL (Invitrogen) for the extraction of RNA according to the manufacturer’s protocol. Both reverse transcription and quantitative PCR were carried out using a two-step M-MLV Platinum SYBR Green qPCR SuperMix-UDG kit (Invitrogen). The Eppendorf realplex4 detection system (Eppendorf, Hamburg, Germany) was used for
quantitative-PCR analysis. The primers of tested genes were synthesized from Invitrogen. The primer sequences used are listed in Table S1, see section on supplementary data given at the end of this article. The amount of each gene was determined and normalized to the amount of β-actin.

**Western immunoblot analysis**

Fifty micrograms of total protein were separated by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis and electrotransferred to a nitrocellulose membrane. Each membrane was pre-incubated for 1 h at room temperature in Tris-buffered saline, pH 7.6, containing 0.05% tween-20 and 5% non-fat milk, and incubated with specific antibodies. Immunoreactive bands were then detected by incubating the membrane with secondary antibodies conjugated to HRP, and visualized using ECL reagents (Bio-Rad). The protein amounts were analyzed using Image J analysis Software version 1.38e (NIH, Bethesda, MD, USA) and normalized with their respective control.

**Statistical analysis**

Each in vitro experiment was performed in a group size of n ≥ 3 independent samples. Representative images from three independent experiments were shown. The results are presented as mean ± s.d. The statistical significance of difference between groups was obtained by student’s t-test or ANOVA multiple comparisons in GraphPad Pro (GraphPad, San Diego, CA, USA). Multiple comparisons between the groups were performed using post-hoc S-N-K method. P < 0.05 was considered as indication of statistical significance.

**Results**

**LG13 strong inhibition on 11β-HSD1 enzyme activity**

As described in our previous papers (Hu et al. 2013, Lin et al. 2013), a series of curcumin analogs have been tested for their inhibitory potency against 11β-HSD1/2 enzyme activity. The results of LG13 are shown in Fig. 1B with curcumin as a comparison. Testis and Leydig cells have extremely high expression and activity of 11β-HSD1. Using rat Leydig cells and microsomes from rat testis, which have high 11β-HSD1 activities, we found that LG13 showed strong inhibitory effects against rat 11β-HSD1, with IC_{50} values of 0.10 and 0.18 μM respectively. We then constructed CHO-hs-HSD11B1 cell line, which over-expresses the HSD11B1 gene and exhibits 11β-HSD1 activity. Low IC_{50} values were also observed when LG13 inhibited 11β-HSD1 activity in CHO cells transfected with HSD11B1. LG13 showed greater potency (8.2- to 57-fold) for the inhibition of 11β-HSD1 activity than curcumin. 11β-HSD2, on the other hand, acts as a dehydrogenase and catalyzes the opposite reaction, down-regulating the activities of GC in kidney and colons. Thus, the rat kidney microsomes were prepared and used for the 11β-HSD2 activity assay. More importantly, compound LG13 did not inhibit rat 11β-HSD2 at all at 100 μM, while curcumin showed slight selectivity for 11β-HSD2 (Fig. 1B). To explore whether LG13 inhibits 11β-HSD1 activity in a microsome-free system, recombinant human 11β-HSD1 protein was incubated with or without LG13 and the enzymatic activity (conversion of 11-dehydrocorticosterone to corticosterone) was tested using HPLC. As shown in Fig. 1C, LG13 also dose-dependently decreased the enzymatic activity of recombinant 11β-HSD1 protein, indicating that LG13 might directly bind 11β-HSD1 and inhibited its activity.

To explain the mode of interaction between LG13 and 11β-HSD1, a molecular docking simulation was performed based on the X-ray crystal structure of the 11β-HSD1 complex with a synthetic and selective inhibitor (PDB structure No. 2IRW). In the initial crystal structure, hydrogen bonds provided strong interactions between the ligand and the protein. As shown in Fig. 1D, the carbonyl group of LG13 formed one hydrogen bond with Ser170 of 11β-HSD1 without NADPH, and the CF3 group of LG13 formed the second hydrogen bond with Ala172. In addition, Tyr177 might be involved in hydrophobic contact with the benzene ring of LG13. However, the conformational shift induced by co-substrate NADPH binding removed the hydrogen bond interactions between LG13 and 11β-HSD1, in which residues Leu126, Tyr183, Tyr177, and Val227 formed a hydrophobic pocket and were involved in the hydrophobic contacts with LG13 (Fig. 1D and E). The docking results also showed that LG13 forms hydrophobic contacts with NADP using respective benzene rings (Fig. 1F).

**Inhibition of 11β-HSD1 enzyme activity by LG13 led to the decrease in 11β-HSD1 expression**

Previous studies showed that GC which is active downstream of 11β-HSD1 could increase 11β-HSD1 expression as a positive feedback to the pathology
(Bujalska et al. 2006, Yang et al. 2009, Zhu et al. 2010, Wang et al. 2013). We then determined whether LG13 could inhibit 11β-HSD1 expression by inhibiting 11β-HSD1 activity. First, we showed that treatment of hepatic HL7702 cells with dexamethasone (DEX, an active GC) for 1 h significantly increased the protein expression of 11β-HSD1 (Fig. 2A) and GR (Fig. 2B). Pretreatment with mifepristone (Mif), a GR antagonist, markedly reversed DEX-induced 11β-HSD1 and GR expression. A previous study also found that incubation with a high concentration of glucose (HG) could increase the expression of 11β-HSD1 (Fan et al. 2011). Thus, we investigated the effects of 11β-HSD1 inhibitors on 11β-HSD1 expression in the HG system. As shown in Fig. 2C and D, HG treatment for 90 min increased the expression of 11β-HSD1 and GR, while the enzyme inhibitors including PF-915275 (PF), a well-known potent 11β-HSD1 inhibitor, and LG13, significantly reduced HG-induced overexpression of 11β-HSD1 itself as well as GR. LG13 also showed a greater inhibitory effect than PF (Fig. 2C and D). These data indicate that there is a positive feedback mechanism in the 11β-HSD1/GR activity-expression pathway, and the down-regulation of 11β-HSD1/GR expression by small molecule inhibitors may be used to investigate their effects on the activity of 11β-HSD1.

**LG13 inhibited prednisone-induced changes, but had no effect on DEX induction**

The data previously shown have demonstrated that LG13 could directly bind and inhibit 11β-HSD1 at the protein, microsome, and cell levels. Here, we further investigated the beneficial effects of LG13 both in vitro and in vivo, which were mediated by its inhibition on 11β-HSD1. DEX is a synthetic active GC directly binding and activating GR, whereas prednisone (PRE) is a synthetic cortisone analogue (inactive GC), which has little affinity for GR (Chapman et al. 2013). However, PRE can be catalyzed by liver 11β-HSD1 to its active metabolite, prednisolone, which acts as an active GC. We detected the effects of LG13 on DEX- and PRE-treated cells and mice respectively.

As shown in Fig. 3A and B, stimulation with both DEX and PRE for 1 h significantly increased the expression of 11β-HSD1 and GR protein in HL7702 cells. Pretreating with LG13 (5 and 10 μM) for 2 h dose-dependently reduced PRE-induced 11β-HSD1 expression, whereas no obvious inhibition was observed in DEX-treated cells. Similar results were observed at the mRNA level (Fig. 3C and D). We next confirmed the selective inhibition of LG13 in mice treated with DEX and PRE. Mice were intraperitoneally injected with DEX or PRE at the indicated dosage for 15 days, with or without oral administration of LG13 at 5 mg/kg. The dosages of DEX and PRE used here are decided in our preliminary experiments, in which we found that prednisone acetate (3 mg/kg per day, i.p.) and dexamethasone (2.5 mg/kg per day, i.p.) led to a comparable pathological induction in mice. Figure 4A shows that both DEX and PRE significantly increased 11β-HSD1 protein expression in mice livers, while oral administration with LG13 inhibited PRE-induced 11β-HSD1 expression by 99.6%. A similar result was observed in hepatic tissue, where LG13 was found to have no effect on the DEX-increased 11β-HSD1 mRNA level (Fig. 4B). A previous study has also demonstrated that

![Figure 2](image-url)  
Inhibition of 11β-HSD1 enzyme activity led to the decrease in 11β-HSD1 expression. (A and B) GR regulated the expression of 11β-HSD1. Liver HL7702 cells were pretreated with vehicle or mifepristone (Mif, 10 μM) for 1 h, then treated with 1 μM DEX for another 1 h. Total protein was extracted and examined by western blotting analysis using specific antibodies. (C and D) PF-915275 and LG13 decreased HG-induced 11β-HSD1 and GR expression. Liver HL7702 cells were pretreated with PF-915275 (10 μM), or LG13 (5 or 10 μM), or vehicle for 2 h, then stimulated with HG (30 mM) for 90 min. Total protein was extracted and examined by western blotting analysis. The column graphs show the normalized optical density from more than three independent experiments (*P<0.05, **P<0.01, ***P<0.001 compared with HG). A full colour version of this figure is available at [http://dx.doi.org/10.1530/JME-14-0268](http://dx.doi.org/10.1530/JME-14-0268).
mice showed glucose intolerance, as evaluated by OGTT, while glucose tolerance was improved by the treatment with LG13, PF, and Piog, at the dosage of 5 mg/kg (Fig. 5B). Plasma glucose tolerance levels, as determined by the area under curve (AUC) of the glucose concentration curve, were reduced by 15.2, 25.7, and 33.6% compared to vehicle control following administration of 5 mg/kg PF, Piog, and LG13 respectively ($P<0.05$, Fig. 5C).

The AKT/PI3K pathway plays an important role in the development of insulin resistance (Glass & Olefsky 2012). As shown in Fig. 5D, the phosphorylation of AKT (also known as protein kinase B) in DM was decreased, while administration of PF, Piog or LG13 all significantly prevented AKT dephosphorylation ($P<0.05$). It has been demonstrated that gene products including insulin receptor substrate (IRS)-1, glucose transporter (GLUT)-4, adiponectin, and fatty acid binding protein (FABP)-4 are involved in the development of hepatic insulin resistance (Becker et al. 2004, Tiikkainen et al. 2004, Subash-Babu et al. 2015). Therefore, these biochemical parameters in mice livers were detected by quantitative real-time PCR. As shown in Fig. 5E, F, G, and H, mice in the DM group had decreased hepatic gene expression of IRS-1, GLUT-4, and adiponectin, but increased FABP-4 mRNA levels. Treatment with LG13 dose-dependently reversed these changes in diabetic mice livers. Interestingly, PF and Piog showed different effects on the above changes compared to LG13.

Administration of LG13 lowered fasting blood glucose, and improved glucose tolerance and hepatic glucose metabolism in type 2 diabetic mice

To validate the beneficial effects of LG13 in vivo, an experimental type 2 diabetic mouse model was established for analyzing the pharmacological functions of LG13. As Fig. 5A shows, LG13 administered by oral gavage for 6 weeks reduced fasting glucose concentrations to 53.8% of the diabetic mice, and these remained significantly lower ($P<0.01$) throughout the treatment period. The glucose-lowering effect of LG13 was dose-dependent and stronger than that of the positive controls of PF and pioglitazone (Piog) at the same dosage (5 mg/kg). The type 2 diabetic

Figure 3
LG13 inhibited prednisone-induced changes, but had no effect on dexamethasone's induction in vitro. Liver HL7702 cells were pretreated with LG13 (5, 10 μM), or DM50 for 2 h, then stimulated with DEX (1 μM) or PRE (1 μM) for 24 h. The expression of 11β-HSD1 and GR were detected by western blot (A and B) or quantitative real-time PCR (C and D) as described in 'Materials and methods' section. Bars represent the mean ± S.E.M. of more than three independent experiments (*$P<0.05$, **$P<0.01$ compared with PRE). A full colour version of this figure is available at http://dx.doi.org/10.1530/JME-14-0268.

GCs can induce insulin resistance and increase blood glucose levels (Macfarlane et al. 2008). As shown in Fig. 4C, induction by either DEX or PRE led to a 1.5-fold increase in fasting blood glucose level in mice ($P<0.01$), while treatment with LG13 only significantly attenuated PRE-induced hyperglycemia, not DEX-induction. This evidence showed LG13 inhibited the PRE-induced changes but had no effect on the downstream DEX's action, indicating that 11β-HSD1 is the direct target of LG13 and mediates the biological effects of LG13 both in vitro and in vivo.

Figure 4
LG13 inhibited prednisone-induced changes, but had no effect on dexamethasone's induction in vitro. After 15 days of treatment, the mice were killed and liver tissues from each group were individually processed for protein and RNA extraction. Relative expression of 11β-HSD1 in livers was detected by western blot (A) and quantitative real-time PCR (B). Before mice were killed, blood glucose level was determined (C) ($n=8$ in each group, *$P<0.05$ compared with PRE group). A full colour version of this figure is available at http://dx.doi.org/10.1530/JME-14-0268.
Figure 5
Administration of LG13 decreased fasting blood glucose, and improved glucose tolerance and hepatic glucose metabolism in type 2 diabetic mice. PF-915275 (PF) and pioglitazone (Piog) at the dosage of 5 mg/kg were used as positive comparison. (A) The fasting blood glucose levels at day 0, 1, 7, 17, 27, 37, and 42 after LG13 administration were monitored (n=8). (B and C) Effect of compounds on OGTT (n=8). After the last treatment with compounds, mice were fasted overnight (12 h), followed by administrated with D-glucose (2 g/kg, p.o.). The blood glucose levels at 0, 15, 30, 60 and 120 min were detected (B), and the area under each curve was calculated respectively (C). The data in A–C were analyzed using Repeated Measures ANOVA. (D) LG13 administration reversed the injured insulin signaling. At the time of death, mice livers were harvested and processed for protein extraction. The levels of p-AKT/AKT were determined by western blot analysis. (E, F, G, and H) Effect of LG13 on insulin resistance-related genes expression. At the time of death, mice livers were harvested and processed for RNA extraction. Relative gene expression of IRS-1 (E), adiponectin (F), GLUT-4 (G), and FABP-4 (H) were detected by quantitative real-time PCR (n=8, *P<0.05, **P<0.01, ***P<0.001 compared with DM group). A full colour version of this figure is available at http://dx.doi.org/10.1530/JME-14-0268.
at the same dosage of 5 mg/kg. PF only reversed the changes of IRS-1 and FABP-4 and FABP-4 overexpression in diabetic livers. These results indicated that 11β-HSD1 inhibitors effectively attenuated hyperglycemia and improved hepatic glucose metabolism in type 2 diabetic mice, and LG13 exhibited stronger pharmacological effects than PF and Piog. In addition, the fact that LG13 could affect AKT phosphorylation and IRS1/GLUT4 expression in diabetic mice indicates that the anti-diabetes effects of 11β-HSD1 inhibitor may be associated with the attenuation of impaired early insulin signaling and the increase in IRS-1/GLUT4 expression which contribute to the basal glucose uptake.

**Metabolic effects of the 11β-HSD1 inhibitor LG13 in the livers of type 2 diabetic mice**

Inhibition of 11β-HSD1 has been shown to improve serum lipid profiles and alleviate fatty liver in mice with metabolic syndrome or type 2 diabetes (Nixon et al. 2012, Stewart & Tomlinson 2009). We next investigated whether LG13 treatment could attenuate such pathological changes. In DM mice, there were significant increases in serum levels of TG, TCh, and LDL-c (Table 1). All of the tested drugs, including PF, Piog, and LG13, lowered the serum levels of these three indexes \((P<0.01)\). LG13 showed a dose-dependent reduction which was greater than that observed with PF and Piog. LG13 at 5 mg/kg also exhibited the inhibition of DM-increased levels of hepatic TG, while no significant attenuation was observed in other treated groups (Table 1). TG levels were reduced by 55 and 31% in the serum and livers of LG13-treated mice respectively. When compared to controls, DM induced a significant increase in the ratio of liver weight to body weight, while PF and LG13 at 5 mg/kg reduced the DM-induced increase in liver weight after 42 days of treatment (Fig. 6A). Further, H&E analysis of liver sections demonstrated that DM-induced hepatic steatosis was substantially attenuated by oral administration of LG13 at 5 mg/kg for 6 weeks (Fig. 6B). The type 2 diabetic mice had increased hepatocellular ballooning degeneration, increased lipid content, inflammatory lesions, and fibrosis when compared to the control administration significantly attenuated hepatic steatosis. At the time of death, mouse liver tissues were processed for H&E staining as described in 'Materials and methods' section (200× amplification).

mice and those diabetic animals received with 5 mg/kg LG13. This change was accompanied by a marked reduction in the serum and liver levels of the liver injury markers ALT and AST (Table 1). However, PF and Piog could not prevent the increase in ALT in diabetic mouse livers. Taken together, the new 11β-HSD1 inhibitor LG13 showed more potent pharmacological effects on abnormal lipid metabolism and fatty liver injury than the positive controls, PF and Piog, at the same dosage.

**Administration of LG13 inhibited the hepatic 11β-HSD1/GR pathway in diabetic mice**

At the time of death, mice livers were harvested for analyzing the protein and gene expression in the 11β-HSD1/GR pathway. As shown in Fig. 7A, B, C, and D, diabetic mice expressed higher levels of 11β-HSD1 and GR in liver tissues, while treatment with PF, Piog, or LG13 (1 or 5 mg/kg) significantly reduced the expression of 11β-HSD1 and GR at both the protein and mRNA levels (P<0.05). As expected, LG13 showed a dose-dependent effect and stronger activity than PF and Piog. GCs are known to increase the expression of two key gluconeogenic enzymes: phosphoenolpyruvate carboxykinase (PEPCK) and catalytic subunit glucose-6-phosphatase (G6Pase), which play important roles in liver glucose homeostasis and insulin sensitivity (Lu et al. 2013). Figure 7E showed that LG13 dose-dependently reduced mRNA levels of PEPCK in livers from 6.42 in the DM group to 1.67 and 1.23 (P<0.01) after the administration at 1 and 5 mg/kg dosage, respectively. The levels of G6Pase mRNA also decreased after LG13 treatment (Fig. 7F).

Although similar results were observed in the PF- and Piog-treated groups, both showed relatively lower inhibition than LG13. These data implied that the anti-diabetic benefits of LG13 are accompanied by its inhibition of the hepatic 11β-HSD1/GR pathway.

**Discussion**

Excess GC accumulation may result in several metabolic syndromes, such as insulin resistance, obesity, and type 2 diabetes, in both animals and humans (Walker 2006). 11β-HSD1 is abundantly expressed in liver and adipose tissues, where it plays a key role in regulation of the local generation of active GCs (Masuzaki et al. 2001, Chapman et al. 2013). Increases in active GCs in liver tissues are closely related with the pathogenesis of metabolic syndromes. Overexpression of 11β-HSD1 in the mouse liver caused active GC excess which induced metabolic disorders, while 11β-HSD1 knockout mice were resistant to high fat diet-induced metabolic syndromes (Harno et al. 2013a,b, Paterson et al. 2004). Thus, pharmacological intervention with 11β-HSD1 is a potential therapeutic method for preventing metabolic diseases. Courtney et al. (2008) reported the activity of PF-915275, a potent and small-molecular 11β-HSD1-selective inhibitor exhibited improvement of hepatic insulin sensitivity and reduction of lipid deposition in type 2 diabetic patients. In addition, three 11β-HSD1 selective inhibitors, AMG221, INCB13739, and DIO-902, are now being investigated in clinical trials (Schwartz et al. 2008, Tiwari 2010, Gibbs et al. 2011).

In previous studies, we firstly reported that curcumin potentially inhibits 11β-HSD1 activity in intact cells (Hu et al. 2013). It exhibited a moderately selective inhibition on 11β-HSD1, two- to fivefold that on 11β-HSD2. Curcumin is a natural active product with multiple pharmacological functions (Asher & Spelman 2013). However, its clinical application has been significantly limited by its fast metabolism and poor bioavailability.
(Epstein et al. 2010). Our lab has designed and synthesized a series of structural analogs of curcumin in order to discover novel agents with stronger 11β-HSD1 inhibition and higher selectivity (Liang et al. 2009a). Of these curcumin analogs, LG13, exhibited strong inhibitory effect and high selectivity against 11β-HSD1 over 11β-HSD2. LG13 is a novel and potent 11β-HSD1 selective inhibitor. With PF-915275s as a positive control, the present study describes the action and mechanism of a novel selective 11β-HSD1 inhibitor, LG13, on glucose homeostasis and hepatic insulin sensitivity in type 2 diabetic mice.

Inactive GCs, such as prednisone, can be catalyzed by 11β-HSD1 into active metabolites, such as prednisolone, which induces hyperglycemia and metabolic syndromes (Courtney et al. 2008). Therefore, theoretically, the 11β-HSD1 inhibitor cannot attenuate the active GC-induced pathological changes. A previous study reported that an 11β-HSD1 inhibitor, emodin, could reverse prednisone-induced insulin resistance in obese mice, but had no effect on dexamethasone induction (Feng et al. 2010). Similar results were observed in the action of LG13. Our data reveal that LG13 only decreased prednisone-induced 11β-HSD1 and GR overexpression, but had no significant effect on those induced by dexamethasone in both hepatic cells and mice models. Subsequently, oral administration of LG13 had little effect on dexamethasone-induced hyperglycemia, while it significantly decreased prednisone-induced hyperglycemia (Fig. 4C). However, the usage of discrepant doses of prednisone and dexamethasone may be a limitation of this study. The dosages used here are referred to our preliminary experiments, in which we found that prednisone acetate (3 mg/kg per day, i.p.) and dexamethasone (2.5 mg/kg per day, i.p.) led to a comparable pathological induction in mice. The dosage difference may be attributed to drug sensitivity, drug metabolism, and salt forming. Although they reached a comparable level in stimulating changes, the data in Fig. 4 showed slightly higher levels of 11β-HSD1 protein and mRNA with dexamethasone than with prednisone treatment. The dosage difference did not influence the conclusion that LG13 inhibited prednisone but not dexamethasone. Therefore, these findings validate that LG13 specifically inhibits 11β-HSD1 and functions by inhibiting 11β-HSD1 in vitro and in vivo.

The phenotype of type 2 diabetes has been associated with increasing hepatic 11β-HSD1 activity. Induction of hepatic 11β-HSD1 activity could increase local active GC production, then directly act on the GR, which is a nuclear receptor regulating genes in development, metabolism, and the immune response (Zhou & Cidlowski 2005, Snyder et al. 2011). Although 11β-HSD1 expression also plays an important role in the development of metabolic syndromes, in recent years pharmacological interventions targeting 11β-HSD1 have mainly focused on the inhibition of 11β-HSD1 enzymatic activity. Several stimuli, including HG, TNF-α, and lipopolysaccharide (LPS) have been shown to stimulate the expression of 11β-HSD1 in different cells (Ishii et al. 2007, Ignatova et al. 2009, Fan et al. 2011). It has been reported that TNF-α-induced 11β-HSD1 expression was mediated by p38 MAPK, cCAAT/enhancer binding protein (C/EBP)-β, and NF-κB pathways (Ignatova et al. 2009). Interestingly, several studies have demonstrated that active GCs have the ability to increase 11β-HSD1 expression (Yang et al. 2009, Zhu et al. 2010). The regulation of GR transcriptional activity on 11β-HSD1 expression is still unclear. In the present study, we found that dexamethasone could significantly induce 11β-HSD1 and GR expression while either mifepristone or LG13 remarkably inhibited dexamethasone-induced 11β-HSD1 and GR expression in hepatic cells (Fig. 2A and B). To our knowledge, this is the first time that 11β-HSD1 inhibitors, such as PF-915275 and LG13, have been shown to not only inhibit 11β-HSD1 activity, but also decrease HG- and hyperglycemia-induced 11β-HSD1 and GR expression in vitro and in vivo (Figs 2C, 7A, and C). This finding reveals the relationship between 11β-HSD1 activity and its own expression, and indicates a possible positive feedback system in the 11β-HSD1/GR cycle.

Further, we found that oral administration of LG13 at 5 mg/kg for 6 weeks significantly decreased fasting blood glucose, hepatic glucose metabolism, histological disorders, and lipid deposition type 2 diabetic mice. Compared with pioglitazone and PF-915275, LG13 exhibited better pharmacological effects. Thus, the novel 11β-HSD1 inhibitor, LG13, is a potential agent for preventing type 2 diabetes. In addition, we also noted that 11β-HSD1 is expressed in other tissues, including adipocytes, muscle, and pancreatic island, which are also in relation to glucose metabolism and insulin resistance. Thus, 11β-HSD1 in other tissues may be also in response to GL13 to regulate glucose metabolism. Here we only demonstrated the 11β-HSD1/GR and pathological changes in diabetic mouse liver. Further study should be carried out to observe the effects of LG13 in other tissues. In summary, this work discovered a positive feedback system for 11β-HSD1 expression and activity, and demonstrated a new 11β-HSD1 inhibitor, LG13, is a potential agent for preventing type 2 diabetes and hepatic glucose metabolism.
